

# ALGEBRAIC FUNCTIONS WITH INFINITELY MANY VALUES IN A NUMBER FIELD

FEDOR PAKOVICH

ABSTRACT. We describe algebraic curves  $X : F(x, y) = 0$  defined over  $\overline{\mathbb{Q}}$  that satisfy the following property: there exist a number field  $k$  and an infinite set  $S \subset k$  such that, for every  $y \in S$ , the roots of the polynomial  $F(x, y)$  belong to  $k$ .

## 1. INTRODUCTION

The Hilbert irreducibility theorem, in its simplest form, states that if  $F(x, y)$  is an irreducible polynomial over  $\mathbb{Q}$ , then for infinitely many integers  $n$ , the polynomial  $F(x, n)$  remains irreducible in  $\mathbb{Q}[x]$ . This result has numerous generalizations, the most relevant for this paper being the following extension to number fields: if  $F(x, y)$  is irreducible over a number field  $k$ , then for infinitely many elements  $\tau$  in the ring of integers  $\mathcal{O}_k$ , the polynomial  $F(x, \tau)$  is irreducible in  $k[x]$ .

The Hilbert irreducibility theorem is equivalent to the statement that, for infinitely many values of  $n$ , the degree of the field  $\mathbb{Q}(x_n)$ , generated by a root  $x_n$  of  $F(x, n)$ , attains the maximum possible degree over  $\mathbb{Q}$ . However, this theorem provides no information about the fields  $\mathbb{Q}(x_n)$  themselves. In particular, the following question is outside the scope of the Hilbert theorem: how many distinct fields can be among  $\mathbb{Q}(x_n)$ ? A closely related question is: how quickly do the degrees of fields generated by adjoining a sequence of such roots  $x_n$  to  $\mathbb{Q}$  grow?

This latter problem was investigated by Dvornicich and Zannier in [5], where they proved that if  $\deg_x F \geq 2$ , then there exist constants  $c$  and  $N_0$ , depending on  $F$ , such that  $\mathbb{Q}(x_1, x_2, \dots, x_N)$  has degree at least  $e^{\frac{cN}{\log N}}$  over  $\mathbb{Q}$  whenever  $N \geq N_0$ . Dvornicich and Zannier's result was later generalized to number fields by Bilu ([1]), who showed that if  $F(x, y)$  is defined over a number field  $k$  of degree  $d$ , then the field obtained by adjoining to  $k$  roots  $x_\tau$  of  $F(x, \tau)$ , where  $\tau$  ranges over all elements of  $\mathcal{O}_k$  with height less than  $B$ , has degree at least  $e^{\frac{cB^d}{\log B}}$  for  $B$  greater than  $B_0$ . For further results in this direction, see [2], [3], and [6].

If, instead of the sequence of fields  $\mathbb{Q}(x_1, x_2, \dots, x_N)$ , one considers the sequence  $\mathbb{Q}(x_{i_1}, x_{i_2}, \dots, x_{i_N})$ , where  $i_1, i_2, \dots, i_N, \dots$  is an arbitrary infinite sequence of integers, the degrees of  $\mathbb{Q}(x_{i_1}, x_{i_2}, \dots, x_{i_N})$  over  $\mathbb{Q}$  do not necessarily grow. For example, if  $F(x, y) = x^r - y$ , then for any  $y$  that is an  $r$ th power of an integer, the roots of the polynomial  $F(x, y)$  belong to the same field  $k$  generated by the  $r$ -th roots of unity. This phenomenon motivates the following general question: for which irreducible algebraic curves  $X : F(x, y) = 0$  over  $\overline{\mathbb{Q}}$  do there exist a number field  $k$  and an infinite set  $S \subset k$  such that, for every  $y \in S$ , the roots of the polynomial  $F(x, y)$  belong to  $k$ ? Defining the  $y_0$ -fiber of a curve  $X : F(x, y) = 0$  as

the set of its points with the second coordinate equal to  $y_0$ , we will refer to curves possessing this property as curves with infinitely many  $y$ -fibers in a number field.

Although the above problem appears quite natural, we have found no literature specifically addressing it and provide a solution in this paper. Furthermore, we show that the problem is equivalent to its seemingly stricter version, in the spirit of arithmetic dynamics, which asks whether there exists a set  $S$  as described above that forms the forward orbit of a point under a rational function.

Notice that the Faltings theorem implies that if  $X$  has infinitely many  $y$ -fibers in a number field, then the genus of  $X$  must be either zero or one. Notice also that any graph  $x = P(y)$ , where  $P \in \overline{\mathbb{Q}}(t)$ , obviously has infinitely many  $y$ -fibers in a number field. Thus, we will always assume that the curves we consider satisfy  $\deg_x F \geq 2$ .

Our main result is the following statement.

**Theorem 1.1.** *Let  $X : F(x, y) = 0$  be an irreducible affine curve over  $\overline{\mathbb{Q}}$  such that  $\deg_x F \geq 2$ . Then the following conditions are equivalent.*

- 1) *The curve  $X$  has infinitely many  $y$ -fibers in a number field.*
- 2) *There exists a rational function  $A$  of degree at least two over  $\overline{\mathbb{Q}}$  satisfying the following condition: for every  $y_0 \in \overline{\mathbb{Q}}$ , there exists a number field  $k$  such that  $y$ -fibers of  $X$  belong to  $k$  for every  $y \in \overline{\mathbb{Q}}$  that belongs to the forward orbit of  $y_0$  under  $A$ .*
- 3) *There exists a self-rational map  $\psi : X \rightarrow X$  of degree at least two, defined over  $\overline{\mathbb{Q}}$ , which maps each  $y$ -fiber of  $X$  bijectively onto another  $y$ -fiber for all but finitely many values  $y \in \mathbb{C}$ .*
- 4) *The Galois closure of the field extension  $\mathbb{C}(X)/\mathbb{C}(y)$  has genus zero or one.*

Notice that the second condition of the theorem clearly implies the first, since we can choose  $y_0$  to be any non-preperiodic point of  $A$ . It is also rather easy to check that a self-rational map satisfying the third condition has the form

$$(1) \quad \psi : (x, y) \mapsto (\varphi(x, y), A(y)),$$

where  $A$  is a rational function of one variable that satisfies the second condition. Thus, the second condition is a corollary of the third. Finally, let us mention that the fourth condition of Theorem 1.1, which strengthens the condition  $g(X) \leq 1$ , can be effectively verified in terms of the ramification of  $y$  alone, and that the function  $A$  in the second condition and the map  $\psi$  in the third condition (more precisely, families of such functions and maps) can also be effectively constructed.

We illustrate Theorem 1.1 with the following two examples (for more details, see Section 2.4). Let  $X : F(x, y) = 0$  be an algebraic curve of genus zero with a generically one-to-one parametrization  $t \mapsto (U(z), V(z))$  by some rational functions  $U$  and  $V$ . Then the fourth condition of the theorem is satisfied for example for the rational function  $V = 3z^4 - 4z^3$ , and the second condition for this  $V$  holds, for instance, for the rational function

$$(2) \quad A = \frac{z^2(z^3 - 240z^2 + 19200z - 512000)}{625z^4 + 16000z^3 + 153600z^2 + 655360z + 1048576}.$$

In particular, if  $U = z$ , then  $X$  is the graph  $V(x) - y = 0$ , and the self-rational map  $\psi$  from the third condition has the form  $(x, y) \rightarrow (B(x), A(y))$ , where

$$(3) \quad B = -\frac{z^2(3z^3 - 10z^2 + 20z - 40)}{15z^4 - 20z^3 + 32}.$$

In this case, the third condition simply means that the functions  $A$ ,  $B$ , and  $V$  make the diagram

$$\begin{array}{ccc} \mathbb{CP}^1 & \xrightarrow{B} & \mathbb{CP}^1 \\ V \downarrow & & \downarrow V \\ \mathbb{CP}^1 & \xrightarrow{A} & \mathbb{CP}^1 \end{array}$$

commutative, and  $B$  sends the roots of  $V(z) = z_0$  to the roots of  $V(z) = A(z_0)$  generically bijectively.

Another example illustrating Theorem 1.1 is given by an elliptic curve in the short Weierstrass form

$$(4) \quad X : y^2 = x^3 + ax + b$$

defined over  $\overline{\mathbb{Q}}$ . It is not difficult to see that, unless  $a = 0$ , such a curve does not satisfy the fourth condition of Theorem 1.1, and thus does not have infinitely many  $y$ -fibers in a number field. On the other hand, Theorem 1.1 implies that curve (4) always has infinitely many  $x$ -fibers in a number field. As a rational function  $A$  in this case one can take for example the Lattès map

$$(5) \quad A = \frac{z^4 - 2az^2 - 8bz + a^2}{4z^3 + 4az + 4b}$$

associated with the multiplication-by-2 endomorphism of  $X$ .

The rest of this paper is organized as follows. First, we recall a construction that describes the Galois closure of the field extension  $\mathbb{C}(X)/\mathbb{C}(y)$  in terms of fiber products. Next, we establish several results about the connection between the fourth condition of Theorem 1.1 and the semiconjugacy relation for holomorphic maps on compact Riemann surfaces. Finally, we prove Theorem 1.1 and provide some examples.

## 2. PROOFS

**2.1. Normalizations and orbifolds.** Let  $C$  be a compact Riemann surface and  $V : C \rightarrow \mathbb{CP}^1$  a holomorphic map. A *normalization* of  $V$  is defined as a compact Riemann surface  $\mathcal{N}_V$  together with a holomorphic Galois covering of the minimal degree  $\tilde{V} : \mathcal{N}_V \rightarrow \mathbb{CP}^1$  such that  $\tilde{V} = V \circ H$  for some holomorphic map  $H : \mathcal{N}_V \rightarrow C$ . The normalization is characterized by the property that the field extension  $\mathcal{M}(\mathcal{N}_V)/\tilde{V}^*(\mathcal{M}(\mathbb{CP}^1))$  is isomorphic to the Galois closure of the extension  $\mathcal{M}(C)/V^*(\mathcal{M}(\mathbb{CP}^1))$ , where  $\mathcal{M}(C)$  denotes the field of meromorphic functions on a compact Riemann surface  $C$  (see e.g. [9], Section 2.9). In particular, if  $X : F(x, y) = 0$  is a curve over  $\mathbb{C}$  and  $C_X$  is its desingularization, that is, a compact Riemann surface  $C_X$  provided with holomorphic maps  $U : C_X \rightarrow \mathbb{CP}^1$  and  $V : C_X \rightarrow \mathbb{CP}^1$  such that the map

$$(6) \quad \theta : t \rightarrow (U(t), V(t)) \subset \mathbb{CP}^1 \times \mathbb{CP}^1$$

is an isomorphism between  $C_X$  and  $X$  outside a finite set, then the condition that the Galois closure of the field extension  $\mathbb{C}(X)/\mathbb{C}(y)$  has genus zero or one is equivalent to the condition that  $g(\mathcal{N}_V)$  equals zero or one.

For a holomorphic map  $V : C \rightarrow \mathbb{CP}^1$  of degree  $n \geq 2$  its normalization can be described in terms of the fiber product of  $V$  with itself  $n$  times as follows (see [8], §I.G or [17], Section 2.2). Let  $\mathcal{L}^V$  be an algebraic variety consisting of  $n$ -tuples of  $C^n$  with a common image under  $V$ ,

$$\mathcal{L}^V = \{(x_i) \in C^n \mid V(x_1) = V(x_2) = \dots = V(x_n)\},$$

and  $\widehat{\mathcal{L}}^V$  a variety obtained from  $\mathcal{L}^V$  by removing components that belong to the big diagonal

$$\Delta^C := \{(x_i) \in C^n \mid x_i = x_j \text{ for some } i \neq j\}$$

of  $C^n$ . Further, let  $\mathcal{L}$  be an arbitrary irreducible component of  $\widehat{\mathcal{L}}^V$  and  $\mathcal{N} \xrightarrow{\theta} \mathcal{L}$  the desingularization map. Finally, let  $\psi : \mathcal{N} \rightarrow \mathbb{CP}^1$  be a holomorphic map induced by the composition

$$\mathcal{N} \xrightarrow{\theta} \mathcal{L} \xrightarrow{\pi_i} C \xrightarrow{V} \mathbb{CP}^1,$$

where  $\pi_i$  is the projection to any coordinate. In this notation, the following statement holds.

**Theorem 2.1.** *The map  $\psi : \mathcal{N} \rightarrow \mathbb{CP}^1$  is the normalization of  $V$ .* □

We recall that a pair  $\mathcal{O} = (R, \nu)$  consisting of a Riemann surface  $R$  and a ramification function  $\nu : R \rightarrow \mathbb{N}$  which takes the value  $\nu(z) = 1$  except at isolated points is called an *orbifold*. For an orbifold  $\mathcal{O}$  the *Euler characteristic* of  $\mathcal{O}$  is the number

$$\chi(\mathcal{O}) = \chi(R) + \sum_{z \in \mathbb{CP}^1} \left( \frac{1}{\nu(z)} - 1 \right),$$

the set of *singular points* of  $\mathcal{O}$  is the set

$$c(\mathcal{O}) = \{z_1, z_2, \dots, z_s, \dots\} = \{z \in \mathbb{CP}^1 \mid \nu(z) > 1\},$$

and the *signature* of  $\mathcal{O}$  is the set

$$\nu(\mathcal{O}) = \{\nu(z_1), \nu(z_2), \dots, \nu(z_s), \dots\}.$$

If  $R_1, R_2$  are Riemann surfaces provided with ramification functions  $\nu_1, \nu_2$ , and  $f : R_1 \rightarrow R_2$  is a holomorphic branched covering map, then  $f$  is called a *covering map*  $f : \mathcal{O}_1 \rightarrow \mathcal{O}_2$  between orbifolds  $\mathcal{O}_1 = (R_1, \nu_1)$  and  $\mathcal{O}_2 = (R_2, \nu_2)$  if for any  $z \in R_1$  the equality

$$\nu_2(f(z)) = \nu_1(z) \deg_z f$$

holds, where  $\deg_z f$  stands for the local degree of  $f$  at the point  $z$ .

A universal covering of an orbifold  $\mathcal{O} = (R, \nu)$  is a covering map between orbifolds  $\theta_{\mathcal{O}} : \tilde{\mathcal{O}} \rightarrow \mathcal{O}$  such that  $\tilde{R}$  is simply connected and  $\tilde{\nu}(z) \equiv 1$ . If  $\theta_{\mathcal{O}}$  is such a map, then there exists a group  $\Gamma_{\mathcal{O}}$  of conformal automorphisms of  $\tilde{R}$  such that the equality  $\theta_{\mathcal{O}}(z_1) = \theta_{\mathcal{O}}(z_2)$  holds for  $z_1, z_2 \in \tilde{R}$  if and only if  $z_1 = \sigma(z_2)$  for some  $\sigma \in \Gamma_{\mathcal{O}}$ . A universal covering exists and is unique up to a conformal isomorphism of  $\tilde{R}$ , unless  $\mathcal{O}$  is the Riemann sphere with one ramified point, or the Riemann sphere with two ramified points  $z_1, z_2$  such that  $\nu(z_1) \neq \nu(z_2)$  (see [7], Section IV.9.12). Abusing notation we will denote by  $\tilde{\mathcal{O}}$  both the orbifold and the Riemann surface  $\tilde{R}$ .

With each holomorphic map  $V : C \rightarrow \mathbb{CP}^1$  one can associate in a natural way two orbifolds  $\mathcal{O}_1^V$  and  $\mathcal{O}_2^V$  setting  $\nu_2^V(z)$  equal to the least common multiple of local degrees of  $f$  at the points of the preimage  $V^{-1}\{z\}$ , and

$$\nu_1^V(z) = \nu_2^V(V(z))/\deg_z V.$$

By construction,  $V : \mathcal{O}_1^V \rightarrow \mathcal{O}_2^V$  is a covering map between orbifolds. Furthermore, since a composition of covering maps  $f : \mathcal{O}_1 \rightarrow \mathcal{O}'$  and  $g : \mathcal{O}' \rightarrow \mathcal{O}_2$  is a covering map

$$g \circ f : \mathcal{O}_1 \rightarrow \mathcal{O}_2$$

(see e.g. [10], Corollary 4.1), the composition

$$V \circ \theta_{\mathcal{O}_1^V} : \widetilde{\mathcal{O}_1^V} \rightarrow \mathcal{O}_2^V$$

is a covering map between orbifolds, implying by the uniqueness of the universal covering that

$$(7) \quad \theta_{\mathcal{O}_2^V} = V \circ \theta_{\mathcal{O}_1^V}.$$

For a holomorphic map  $V : C \rightarrow \mathbb{CP}^1$ , the condition  $g(\mathcal{N}_V) \leq 1$  can be expressed merely in terms of  $\chi(\mathcal{O}_2^V)$  as follows (see [11], Lemma 2.6).

**Lemma 2.2.** *Let  $C$  be a compact Riemann surface and  $V : C \rightarrow \mathbb{CP}^1$  a holomorphic map. Then  $g(\mathcal{N}_V) = 0$  if and only if  $\chi(\mathcal{O}_2^V) > 0$ , and  $g(\mathcal{N}_V) = 1$  if and only if  $\chi(\mathcal{O}_2^V) = 0$ .  $\square$*

Notice that orbifolds with  $\chi(\mathcal{O}) \geq 0$  and corresponding  $\Gamma_{\mathcal{O}}$  and  $\theta_{\mathcal{O}}$  can be described explicitly as follows. The equality  $\chi(\mathcal{O}) = 0$  holds if and only if the signature of  $\mathcal{O}$  belongs to the list

$$(8) \quad \{2, 2, 2, 2\} \quad \{3, 3, 3\}, \quad \{2, 4, 4\}, \quad \{2, 3, 6\},$$

while  $\chi(\mathcal{O}) > 0$  if and only if either  $\mathcal{O}$  is the non-ramified sphere or the signature of  $\mathcal{O}$  belongs to the list

$$(9) \quad \{n, n\}, \quad n \geq 2, \quad \{2, 2, n\}, \quad n \geq 2, \quad \{2, 3, 3\}, \quad \{2, 3, 4\}, \quad \{2, 3, 5\}.$$

Groups  $\Gamma_{\mathcal{O}} \subset \text{Aut}(\mathbb{C})$  corresponding to orbifolds  $\mathcal{O}$  with signatures (8) are generated by translations of  $\mathbb{C}$  by elements of some lattice  $L \subset \mathbb{C}$  of rank two and the rotation  $z \rightarrow \varepsilon z$ , where  $\varepsilon$  is an  $n$ th root of unity with  $n$  equal to 2, 3, 4, or 6, such that  $\varepsilon L = L$ . Accordingly, the functions  $\theta_{\mathcal{O}}$  may be written in terms of the corresponding Weierstrass functions as  $\wp(z)$ ,  $\wp'(z)$ ,  $\wp^2(z)$ , and  $\wp'^2(z)$  (see [18], or [7], Section IV.9.5). Groups  $\Gamma_{\mathcal{O}} \subset \text{Aut}(\mathbb{CP}^1)$  corresponding to orbifolds  $\mathcal{O}$  with signatures (9) are the well-known five finite subgroups  $C_n$ ,  $D_{2n}$ ,  $A_4$ ,  $S_4$ ,  $A_5$  of  $\text{Aut}(\mathbb{CP}^1)$ , and the functions  $\theta_{\mathcal{O}}$  are Galois coverings of  $\mathbb{CP}^1$  by  $\mathbb{CP}^1$  of degrees  $n$ ,  $2n$ , 12, 24, 60, calculated for the first time by Klein.

By Lemma 2.2 and equality (7), for a holomorphic map  $V : C \rightarrow \mathbb{CP}^1$  the inequality  $g(\mathcal{N}_V) \geq 0$  holds if and only if  $V$  is a “compositional left factor” of one of the functions  $\theta_{\mathcal{O}}$  described above. Notice that this condition is very restrictive. In particular, rational functions  $V$  for which  $g(\mathcal{N}_V) = 0$  can be listed explicitly. On the other hand, the simplest examples of rational functions with  $g(\mathcal{N}_V) = 1$  are Lattès maps (see [14]).

**2.2. Semiconjugacies over  $\overline{\mathbb{Q}}$ .** A detailed description of the solutions to the functional equation

$$A \circ V = V \circ B,$$

where  $A$ ,  $B$ , and  $X$  are holomorphic maps on compact Riemann surfaces, was obtained in a series of papers [10], [13], [15], [16]. The result below partially follows from the analysis in these papers. However, since we require an additional conclusion concerning definability over  $\overline{\mathbb{Q}}$ , we provide a complete proof, focusing on the existence of some  $A$  and  $B$  with the desired properties rather than on their full description.

**Theorem 2.3.** *Let  $C$  be a compact Riemann surface and  $V : C \rightarrow \mathbb{CP}^1$  a holomorphic map such that  $\chi(\mathcal{O}_2^V) \geq 0$  and  $c(\mathcal{O}_2^V) \subset \overline{\mathbb{Q}}$ . Then there exist holomorphic maps  $A$  and  $B$  of degree at least two such that the diagram*

$$(10) \quad \begin{array}{ccc} C & \xrightarrow{B} & C \\ \downarrow V & & \downarrow V \\ \mathbb{CP}^1 & \xrightarrow{A} & \mathbb{CP}^1 \end{array}$$

*commutes, the compositum of the subfields  $V^*\mathcal{M}(\mathbb{CP}^1)$  and  $B^*\mathcal{M}(C)$  of  $\mathcal{M}(C)$  is the whole field  $\mathcal{M}(C)$ , and  $A$  is defined over  $\overline{\mathbb{Q}}$ .*

*Proof.* We start by observing that if the degrees of the maps  $B$  and  $V$  in (10) are coprime, then the condition

$$(11) \quad V^*\mathcal{M}(\mathbb{CP}^1) \cdot B^*\mathcal{M}(C) = \mathcal{M}(C)$$

is automatically satisfied. Indeed, this condition can be restated as requiring that the equalities

$$V = \widehat{V} \circ T, \quad B = \widehat{B} \circ T,$$

where

$$T : C \rightarrow \widetilde{C}, \quad \widehat{V} : \widetilde{C} \rightarrow \mathbb{CP}^1, \quad \widehat{B} : \widetilde{C} \rightarrow C,$$

are holomorphic maps between compact Riemann surfaces, imply that  $\deg T = 1$ . Since  $\deg T$  divides both  $\deg V$  and  $\deg B$ , the coprimality of  $\deg V$  and  $\deg B$  ensures that this is true.

Assume first that  $\chi(\mathcal{O}_2^V) > 0$ . In this case  $\widetilde{\mathcal{O}}_2^V$  and hence  $C$  is the sphere and the functions  $\theta_{\mathcal{O}_2^V}$  and  $\theta_{\mathcal{O}_1^V}$  related by equality (7) are rational Galois coverings. Moreover, without loss of generality we may assume that  $c(\mathcal{O}_2^V) = \{0, \infty\}$  if  $\nu(\mathcal{O}_2^V) = \{n, n\}$ ,  $n \geq 2$ , and  $c(\mathcal{O}_2^V) = \{0, 1, \infty\}$  otherwise. Indeed, since critical values of  $V$  are algebraic numbers, there exists a Möbius map  $\nu$  with algebraic coefficients that maps these values to  $\{0, 1, \infty\}$ , and if  $A$  satisfies the conclusions of the theorem for  $\nu \circ V$ , then  $\nu^{-1} \circ A \circ \nu$  satisfies them for  $V$ . Thus, below we always will assume that

$$c(\mathcal{O}_2^V) \subseteq \{0, 1, \infty\}.$$

Let us also observe that for a given rational function  $V$ , we can fix  $\theta_{\mathcal{O}_2^V}$  in (7) to be any of representatives of (7), which are defined up to the change  $\theta_{\mathcal{O}_2^V} \rightarrow \theta_{\mathcal{O}_2^V} \circ \mu$ , where  $\mu$  is a Möbius transformation. Thus, below we will use such well-known representatives.

If  $\nu(\mathcal{O}_2^V) = \{n, n\}$ ,  $n \geq 2$ , then as  $\theta_{\mathcal{O}_2^V}$  in (7) we can take  $\theta_{\mathcal{O}_2^V} = z^n$ , and (7) implies that  $V = t^n \circ \mu$ , where  $\mu$  is a Möbius transformation. Setting now

$$A = t^m, \quad B = \mu^{-1} \circ t^m \circ \mu,$$

we see that (10) holds and  $A$  is defined over  $\overline{\mathbb{Q}}$ . Moreover, if  $\text{GCD}(m, n) = 1$ , then (11) also holds.

Further, if  $\nu(\mathcal{O}_2^V) = \{2, 2, n\}$ ,  $n \geq 2$ , then as  $\theta_{\mathcal{O}_2^V}$  we can take

$$\theta_{\mathcal{O}_2^V} = \frac{1}{2} \left( t^n + \frac{1}{t^n} \right),$$

implying by (7) that either

$$V = \frac{1}{2} \left( t^n + \frac{1}{t^n} \right) \circ \mu,$$

or  $V = T_n \circ \mu$ , where  $T_n$  is the  $n$ th Chebyshev polynomial and  $\mu$  is a Möbius transformations (see e.g. [14], Section 4.2). Setting now

$$A = T_m, \quad B = \mu^{-1} \circ t^m \circ \mu,$$

in the first case, and

$$A = T_m, \quad B = \mu^{-1} \circ T_m \circ \mu$$

in the second, and requiring that  $\text{GCD}(m, n) = 1$ , we see that (10) and (11) hold.

Assume now that  $\nu(\mathcal{O}_2^V) = \{2, 3, 4\}$ . Then as  $\theta_{\mathcal{O}_2^V}$  in (7) we can take the function

$$(12) \quad \theta_{\mathcal{O}_2^V} = -\frac{(z^8 + 14z^4 + 1)^3}{108z^4(z^4 - 1)^4},$$

for which the corresponding group  $\Gamma_{\mathcal{O}}$  is generated by the Möbius transformations

$$(13) \quad z \rightarrow iz, \quad z \rightarrow \frac{z+i}{z-i}.$$

In this case, the existence of the required  $A$  and  $B$  can be deduced from the fact that the rational function

$$(14) \quad F = \frac{-z^5 + 5z}{5z^4 - 1},$$

found in [12], satisfies the following properties: the degree of  $F$  is coprime to

$$\deg \theta_{\mathcal{O}_2^V} = |S_4| = 24,$$

and  $F$  is  $\Gamma_{\mathcal{O}_2^V}$ -equivariant, meaning it satisfies the equality

$$(15) \quad F \circ \sigma = \sigma \circ F$$

for every  $\sigma \in \Gamma_{\mathcal{O}_2^V}$ .

Indeed, it follows from (15) that  $F$  maps orbits of  $\Gamma_{\mathcal{O}_2^V}$  to orbits of  $\Gamma_{\mathcal{O}_2^V}$ , and orbits of  $\Gamma_{\mathcal{O}_1^V}$  to orbits of  $\Gamma_{\mathcal{O}_1^V}$ , as  $\Gamma_{\mathcal{O}_1^V}$  is a subgroup of  $\Gamma_{\mathcal{O}_2^V}$ . Since the orbits of  $\Gamma_{\mathcal{O}_2^V}$  and  $\Gamma_{\mathcal{O}_1^V}$  coincide with the fibers of  $\theta_{\mathcal{O}_2^V}$  and  $\theta_{\mathcal{O}_1^V}$ , respectively, this implies that there exist rational functions  $A$  and  $B$  such that the diagrams

$$(16) \quad \begin{array}{ccc} \mathbb{CP}^1 & \xrightarrow{F} & \mathbb{CP}^1 \\ \theta_{\mathcal{O}_2^V} \downarrow & & \downarrow \theta_{\mathcal{O}_2^V} \\ \mathbb{CP}^1 & \xrightarrow{A} & \mathbb{CP}^1 \end{array} \quad \begin{array}{ccc} \mathbb{CP}^1 & \xrightarrow{F} & \mathbb{CP}^1 \\ \theta_{\mathcal{O}_1^V} \downarrow & & \downarrow \theta_{\mathcal{O}_1^V} \\ \mathbb{CP}^1 & \xrightarrow{B} & \mathbb{CP}^1 \end{array}$$

commute. Furthermore, it follows from (16) and (7) that

$$A \circ V \circ \theta_{\mathcal{O}_1^V} = V \circ \theta_{\mathcal{O}_1^V} \circ F = V \circ B \circ \theta_{\mathcal{O}_1^V},$$

implying that the diagram (10) also commutes. In addition, since  $F$  and  $\theta_{\mathcal{O}_2^V}$  are defined over  $\overline{\mathbb{Q}}$ , the first diagram in (16) determines the coefficients of  $A$  through a system of linear equations over  $\overline{\mathbb{Q}}$ . Since this system has at most one solution, we conclude that  $A$  is also defined over  $\overline{\mathbb{Q}}$ . Finally, since

$$\deg V \mid \deg \theta_{\mathcal{O}_2^V} = 24$$

by (7), the degrees  $\deg V$  and  $\deg F$  are coprime.

If  $\nu(\mathcal{O}_2^V) = \{2, 3, 5\}$ , the proof also can be deduced solely from the existence of  $\theta_{\mathcal{O}_2^V}$ , defined over  $\overline{\mathbb{Q}}$ , and a rational function  $F$ , also defined over  $\overline{\mathbb{Q}}$ , which is  $\Gamma_{\mathcal{O}_2^V}$ -equivariant and whose degree is coprime to

$$\deg \theta_{\mathcal{O}_2^V} = |A_5| = 60.$$

Examples of such functions, as well as a description of all  $\Gamma_{\mathcal{O}_2^V}$ -equivariant functions, can be found in [4]. For instance, the function  $f_{11}$  of degree 11 given on p. 166 of [4] is a valid choice for  $F$ .

To complete the proof in the case  $\chi(\mathcal{O}_2^V) > 0$ , observe that, since  $A_4 \subset S_4$ , for the remaining signature  $\nu(\mathcal{O}_2^V) = \{2, 3, 3\}$ , we can choose the corresponding function  $\theta_{\mathcal{O}_2^V}$  to be a compositional right factor of the function (12). Consequently, the function  $F$ , defined by (14), remains  $\Gamma_{\mathcal{O}_2^V}$ -equivariant for  $\nu(\mathcal{O}_2^V) = \{2, 3, 3\}$ , and can be used to complete the proof. Alternatively, since  $A_4 \subset A_5$ , one may instead use the function  $f_{11}$ .

In case  $\chi(\mathcal{O}_2^V) = 0$ , the proof proceeds in a similar way. Assume, for example, that  $\nu(\mathcal{O}_2^V) = \{2, 2, 2, 2\}$ . Then  $\theta_{\mathcal{O}_2^V}$  is equal to the Weierstrass function  $\wp(t)$ , and the group  $\Gamma_{\mathcal{O}} \subset \text{Aut}(\mathbb{C})$  is generated by translations of  $\mathbb{C}$  by elements of some lattice  $L \subset \mathbb{C}$  of rank two, along with the rotation  $z \mapsto -z$ . Since the multiplication by  $m$  on  $\mathbb{C}$  maps the orbits of  $\Gamma_{\mathcal{O}_2^V}$  to the orbits of  $\Gamma_{\mathcal{O}_2^V}$ , and the orbits of  $\Gamma_{\mathcal{O}_1^V}$  to the orbits of  $\Gamma_{\mathcal{O}_1^V}$ , arguing as above, we conclude that there exist holomorphic maps  $A$  and  $B$  that make the diagrams

$$\begin{array}{ccc} \mathbb{C} & \xrightarrow{F=mz} & \mathbb{C} \\ \theta_{\mathcal{O}_2^V} \downarrow & & \downarrow \theta_{\mathcal{O}_2^V} \\ \mathbb{CP}^1 & \xrightarrow{A} & \mathbb{CP}^1 \end{array} \quad \begin{array}{ccc} \mathbb{C} & \xrightarrow{F=mz} & \mathbb{C} \\ \theta_{\mathcal{O}_1^V} \downarrow & & \downarrow \theta_{\mathcal{O}_1^V} \\ C & \xrightarrow{B} & C \end{array}$$

and (10) commutative. Furthermore, since  $\deg A = \deg B = m^2$ , the degrees of  $B$  and  $V$  are coprime whenever  $m$  and  $\deg V$  are coprime.

To prove that  $A$  is defined over  $\overline{\mathbb{Q}}$ , we consider the algebraic curve  $X$  in the short Weierstrass form (4), parametrized by  $\wp(t)$  and  $\wp'(t)$ . Since (7) implies that the critical values of  $V$  coincide with those of  $\wp(t)$ , which are roots of the polynomial in the right part of (4), it follows from the assumption  $c(\mathcal{O}_2^V) \subset \overline{\mathbb{Q}}$  that  $X$  is defined over  $\overline{\mathbb{Q}}$ . Further, it is clear that the multiplication by  $m$  on  $\mathbb{C}$  induces a self-rational map of  $X$  of the form

$$\psi : (x, y) \mapsto (A(x), R(x, y)),$$

where the first coordinate is the function  $A$  under consideration. Finally, since the addition operation on  $X$  is defined over the field of definition of  $X$ , this self-rational map, and in particular the function  $A$ , are also defined over  $\overline{\mathbb{Q}}$ .

Further, if  $\nu(\mathcal{O}_2^V) = \{3, 3, 3\}$ , then  $\theta_{\mathcal{O}_2^V} = \wp'(t)$  and the group  $\Gamma_{\mathcal{O}} \subset \text{Aut}(\mathbb{C})$  is generated by translations of  $\mathbb{C}$  by elements of a triangular lattice  $L \subset \mathbb{C}$  and the rotation  $z \rightarrow \varepsilon z$ , where  $\varepsilon z$  is the 3rd root of unity. In this case, the proof goes similarly with the only exception that now the required  $A$  is given by the second coordinate of the self-rational map of  $X$ , induced by the multiplication by  $m$  on  $\mathbb{C}$ .

Consider finally the case  $\nu(\mathcal{O}_2^V) = \{2, 4, 4\}$ ; the case  $\nu(\mathcal{O}_2^V) = \{2, 3, 6\}$  can be considered by an obvious modification. In this case,  $\theta_{\mathcal{O}_2^V} = \wp^2(t)$ , and, as above, the multiplication by  $m$  on  $\mathbb{C}$  leads to holomorphic maps  $\tilde{B}$  and  $A$  that make diagram (10) commutative. To show now that  $A$  is defined over  $\overline{\mathbb{Q}}$ , we observe that by what is proved above

$$\wp(mz) = \tilde{A} \circ \wp(z)$$

for some rational function  $\tilde{A}$  defined over  $\overline{\mathbb{Q}}$ . Therefore, it follows from

$$\wp^2(mz) = A \circ \wp^2(z)$$

that

$$z^2 \circ \tilde{A} \circ \wp = A \circ z^2 \circ \wp,$$

implying that

$$z^2 \circ \tilde{A} = A \circ z^2.$$

Since the functions  $z^2$  and  $\tilde{A}$  are defined over  $\overline{\mathbb{Q}}$ , we conclude as above that the same is true for the function  $A$ .  $\square$

Our proof of Theorem 2.3 follows the proof of a similar existence statement over the field  $\mathbb{C}$  given in [12]. Notice, however, that the proof in [12] contains an erroneous claim that the function  $f_{11}$  commutes with all the groups  $A_4$ ,  $S_4$ , and  $A_5$ . Since  $S_4 \not\subset A_5$ , this is not true for  $S_4$ , and a different  $S_4$ -equivariant function is needed to prove the theorem for  $\nu(\mathcal{O}_2^V) = \{2, 3, 4\}$ . For example, one can use the function (14) mentioned above, which is found in the same paper [12].

**2.3. Proof of Theorem 1.1.** To prove the implication  $1) \Rightarrow 4)$ , let us consider an algebraic curve  $\mathcal{E}$  in the space  $\mathbb{C}^{2n}$  with coordinates  $(x_1, y_1, x_2, y_2, \dots, x_n, y_n)$  defined by the equations

$$F(x_1, y_1) = F(x_2, y_2) = \dots = F(x_n, y_n) = 0, \quad y_1 = y_2 = \dots = y_n.$$

Since the map (6) is an isomorphism off a finite set, the map

$$(17) \quad (\theta, \theta, \dots, \theta) : C_X^n \rightarrow X^n \subset (\mathbb{CP}^1)^{2n}$$

induces an isomorphism between components of the curve  $\mathcal{L}^V \subset C_X^n$  defined above and components of the curve  $\mathcal{E} \subset X^n$ . On the other hand, it is easy to see that the first condition of the theorem implies that the image of  $\hat{\mathcal{L}}^V$  under (17) has infinitely many points over  $k$ . Therefore, at least one of irreducible components of this image also has infinitely many points over  $k$ . Thus, the fourth condition of the theorem holds by Theorem 2.1 and the Faltings theorem.

To prove the implication  $4) \Rightarrow 3)$ , let us observe that since  $X$  is defined over  $\overline{\mathbb{Q}}$ , critical values of  $U$  and  $V$  in the map (6) are algebraic. In addition, by Lemma 2.2, the inequality  $\chi(\mathcal{O}_2^V) \geq 0$  holds. Thus, Theorem 2.3 is applied to  $V$ , and the map

$B$  in (10) obviously descends to a self-rational map  $\psi$  of  $X$  that makes the diagram

$$(18) \quad \begin{array}{ccc} C_X & \xrightarrow{B} & C_X \\ (U,V) \downarrow & & \downarrow (U,V) \\ X & \xrightarrow{\psi} & X \end{array}$$

commutative and has the form

$$(19) \quad \psi : (x, y) \rightarrow (R(x, y), A(y)),$$

where  $R(x, y)$  is a rational function over  $\mathbb{C}$ . Clearly,  $\psi$  maps  $y$ -fibers to  $y$ -fibers. Moreover,  $R(x, y)$  can be chosen to be defined over  $\overline{\mathbb{Q}}$ . Indeed, if  $\deg V = n$ , then  $R(x, y)$  can be represented on  $X$  by some rational function  $\hat{R}(x, y)$  of the form

$$(20) \quad \hat{R}(x, y) = P_0(y) + P_1(y)x + P_2(y)x^2 + \cdots + P_{n-1}(y)x^{n-1},$$

where  $P_i$ ,  $0 \leq i \leq n-1$ , are rational functions over  $\mathbb{C}$ . Since  $X$  and  $A$  are defined over  $\overline{\mathbb{Q}}$ , there exists an infinite sequence of algebraic points  $(x_j, y_j)$ ,  $j \geq 1$ , on  $X$  such that

$$\hat{R}(x_j, y_j) = (x_{j+1}, y_{j+1}), \quad j \geq 1.$$

Thus, coefficients of  $\hat{R}(x, y)$  satisfy a system of linear equations over  $\overline{\mathbb{Q}}$ . Furthermore, since any function of the form (20) may have only finitely many zeroes on  $X$ , this system has a unique solution, implying that coefficients of  $\hat{R}(x, y)$  belong to  $\overline{\mathbb{Q}}$ .

Finally, it follows from (11) by the primitive element theorem that

$$(21) \quad \mathcal{M}(C) = V^*\mathcal{M}(\mathbb{CP}^1)[h]$$

for some  $h \in B^*\mathcal{M}(C)$ . As elements of  $\mathcal{M}(C)$  separate points of  $C$ , equality (21) implies that for all but finitely many  $z_0 \in C$  the map  $h$  takes  $\deg V$  distinct values on the set  $V^{-1}\{z_0\}$ . Since  $h \in B^*\mathcal{M}(C)$ , this yields that for all but finitely many  $z_0 \in C$  the map  $B$  takes  $\deg V$  distinct values on  $V^{-1}\{z_0\}$ . By (18), this implies in turn that the map induced by  $\psi$  on  $y$ -fibers is generically bijective.

To prove the implication 3)  $\Rightarrow$  2), let us observe that the self-rational map  $\psi : X \rightarrow X$  can be lifted to some holomorphic map  $B : C_X \rightarrow C_X$  that makes the diagram (18) commutative. Moreover, since  $\psi$  sends  $y$ -fibers of  $X$  to  $y$ -fibers,  $B$  maps  $V$ -fibers to  $V$ -fibers, implying that diagram (10) commutes for some rational function  $A$ , and  $\psi$  can be represented in the form (19). Furthermore, since  $X$  and  $\psi$  are defined over  $\overline{\mathbb{Q}}$ , there exists an infinite sequence of algebraic points  $y_j$ ,  $j \geq 1$ , such that  $A(y_j) = y_{j+1}$ , which implies that  $A$  is also defined over  $\overline{\mathbb{Q}}$ .

It is clear that to prove the second condition for the rational map  $A$  and a point  $y_0$  it is enough to prove it for some iterate  $A^{\circ k}(y_0)$ ,  $k \geq 1$ , of  $y_0$ . Thus, without loss of generality we may assume that for all points  $y$  of the forward  $A$ -orbit of  $y_0$  the map on  $y$ -fibers induced by  $\psi$  is bijective. Let us set  $y_i = A^{\circ i}(y_0)$ ,  $i \geq 0$ , and let  $k_0$  be a number field that contains the coefficients of  $R(x, y)$  and  $A(y)$ . By the assumptions, the roots  $\zeta_1^i, \zeta_2^i, \dots, \zeta_n^i$  of  $F(x, y_i)$ ,  $i \geq 0$ , are distinct and satisfy

$$\zeta_1^{i+1} = R(\zeta_1^i, y_i), \quad \zeta_2^{i+1} = R(\zeta_2^i, y_i), \quad \dots, \quad \zeta_n^{i+1} = R(\zeta_n^i, y_i),$$

implying inductively that  $y_i$ -fibers of  $X$  belong to the field  $k = k_0(\zeta_1^0, \zeta_2^0, \dots, \zeta_n^0, y_0)$  for every  $i \geq 0$ . Finally, since a finitely generated algebraic extension is finite,  $k$  is a number field.

Eventually, the implication  $2) \Rightarrow 1)$  is essentially obvious since we can take  $y_0$  to be any non-preperiodic point of  $A$  (notice that by the Northcott theorem such a point exists in any number field).  $\square$

Theorem 1.1 implies the following corollary.

**Corollary 2.4.** *Let  $V$  be a rational function over  $\overline{\mathbb{Q}}$ . Then the roots of the equation  $V(x) = t$  belong to some number field  $k$  for infinitely many  $t \in \overline{\mathbb{Q}}$  if and only if  $\chi(\mathcal{O}_2^V) \geq 0$ .*

*Proof.* To reduce Corollary 2.4 to Theorem 1.1, it is enough to observe that if the first condition of the corollary is satisfied, then the corresponding values of  $t$  belong to the field  $\tilde{k}$  obtained from  $k$  by adjoining coefficients of  $V$ . Thus,  $\tilde{k}$  is a number field, and the curve  $V(x) - y = 0$  has infinitely many  $y$ -fibers in  $\tilde{k}$ .  $\square$

**2.4. Examples.** To give an example to Corollary 2.4, let us consider an orbifold  $\mathcal{O}$ , defined by

$$(22) \quad \nu(0) = 2, \quad \nu(1) = 3, \quad \nu(\infty) = 3,$$

and its universal covering  $\theta_{\mathcal{O}}$ , given by the formula (12). Since the corresponding group  $\Gamma_{\mathcal{O}}$  is generated by the Möbius transformations (13), and the fibers of  $\theta_{\mathcal{O}}$  coincide with the orbits of  $\Gamma_{\mathcal{O}}$ , we see that for any  $z_0$  that belongs to a number field  $k$ , all the roots of  $\theta_{\mathcal{O}}(z) = \theta_{\mathcal{O}}(z_0)$  belong to the number field  $k[i]$ . Thus, the roots of  $\theta_{\mathcal{O}}(z) = t$  belong to  $k[i]$ , whenever  $t \in \theta_{\mathcal{O}}(k)$ . Furthermore, the first diagram in (16) commutes for the functions  $A$  and  $F$  given by (2) and (14). Thus,  $F$  sends the roots of  $\theta_{\mathcal{O}}(z) = z_0$  to the roots of  $\theta_{\mathcal{O}}(z) = A(z_0)$  generically bijectively.

A less obvious example is given by the rational function

$$(23) \quad V = 3z^4 - 4z^3$$

mentioned in the introduction, for which the orbifold  $\mathcal{O}$  defined by (22) serves as  $\mathcal{O}_2^V$ . One can check that for this function, the relation (7) holds for

$$\theta_{\mathcal{O}_1^V} = \frac{\left(\frac{1}{6}(1+i)z^2 - \frac{i}{3}z + \frac{1}{6}(1-i)\right) (z^4 + 2z^3 + 2z^2 - 2z + 1)}{(z^2 + 1)(z + 1)(z - 1)z},$$

and the diagram (10) commutes for the functions  $A$  and  $B$  given by (2) and (3). Thus,  $B$  sends the roots of  $V(z) = z_0$  to the roots of  $V(z) = A(z_0)$  generically bijectively.

Furthermore, any algebraic curve  $X : F(x, y) = 0$  of genus zero with a generically one-to-one parametrization by some rational function  $U$  and the function  $V$  given by (23), has infinitely many  $y$ -fibers in a number field. To construct for such  $X$  the endomorphism  $\psi$ , let us observe that substituting  $B(z)$  for  $z$  into

$$F(U(z), V(z)) = 0$$

and using (10) we derive

$$F(U \circ B(z), A \circ V(z)) = 0.$$

Therefore, the required self-rational map (1) is obtained by expressing the function  $U \circ B$  in the form  $U \circ B = \varphi(U, V)$  for some rational function  $\varphi(x, y)$  over  $\overline{\mathbb{Q}}$ .

As another example, let us consider an elliptic curve given in the short Weierstrass form

$$(24) \quad X : y^2 = x^3 + ax + b, \quad a, b \in \overline{\mathbb{Q}},$$

where  $4a^3 + 27b^2 \neq 0$ . Clearly, the functions  $U$  and  $V$  in (6) have degrees two and three respectively, and, since  $g(X) = 1$ , it follows from Lemma 2.2 that the fourth condition of Theorem 1.1 is satisfied if and only if  $c(\mathcal{O}_2^V)$  belongs to the list (8). Moreover, since  $V$  has a critical point of multiplicity three over infinity, and the least common multiple of local degrees of a map  $V$  of degree three at the points of the preimage  $V^{-1}\{z\}$  cannot be equal six, the only case  $c(\mathcal{O}_2^V) = \{3, 3, 3\}$  is possible. The last condition is equivalent to the condition that for some points  $\pm y_0 \in \mathbb{C}$ , the polynomial

$$x^3 + ax + (b - y_0^2)$$

has a root of multiplicity two, which in turn is equivalent to the condition  $a = 0$ . Thus, we conclude that  $X$  has infinitely many  $y$ -fibers in a number field if and only if  $a = 0$ .

Finally, let us observe that Theorem 1.1 implies that the curve (24) always has infinitely many  $x$ -fibers in a number field. Indeed, since any extension of degree two is Galois, for the corresponding map  $U$ , we have  $\tilde{U} = U$  and  $\mathcal{N}_U = C_X$ . Thus,  $g(\mathcal{N}_U) = g(C_X) = 1$ . As a function  $A$  in this case we can take the Lattès map  $A$  given by the formula (5), which is defined by the commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{\psi} & X \\ \pi \downarrow & & \downarrow \pi \\ \mathbb{CP}^1 & \xrightarrow{A} & \mathbb{CP}^1, \end{array}$$

where  $\pi$  is the projection map on the  $x$ -coordinate and  $\psi$  is the multiplication-by-2 endomorphism of  $X$ .
